10.0 IMPORTANT INFORMATION AND LIMITATIONS OF THIS REPORT

Golder has prepared this report in a manner consistent with the level of care and skill ordinary exercised by members of the archaeological profession currently practicing under similar conditions in the jurisdiction in which the services are provided, subject to the time limits and physical constraints applicable to this report. No other warranty, expressed or implied is made.

This report has been prepared for the specific site, design objective, developments and purpose described to Golder by Ms. Becky Grieve of AECOM. The factual data, interpretations and recommendations pertain to a specific project as described in this report and are not applicable to any other project or site location.

The information, recommendations and opinions expressed in this report are for the sole benefit of the Client. No other party may use or rely on this report or any portion thereof without Golder's express written consent. If the report was prepared to be included for a specific permit application process, then upon the reasonable request of the client, Golder may authorize in writing the use of this report by the regulatory agency as an Approved User for the specific and identified purpose of the applicable permit review process. Any other use of this report by others is prohibited and is without responsibility to Golder. The report, all plans, data, drawings and other documents as well as electronic media prepared by Golder are considered its professional work product and shall remain the copyright property of Golder, who authorizes only the Client and Approved Users to make copies of the report, but only in such quantities as are reasonably necessary for the use of the report by those parties. The Client and Approved Users may not give, lend, sell, or otherwise make available the report or any portion thereof to any other party without the express written permission of Golder. The Client acknowledges that electronic media is susceptible to unauthorized modification, deterioration and incompatibility and therefore the Client cannot rely upon the electronic media versions of Golder's report or other work products.

Unless otherwise stated, the suggestions, recommendations and opinions given in this report are intended only for the guidance of the Client in the design of the specific project.

Special risks occur whenever archaeological investigations are applied to identify subsurface conditions and even a comprehensive investigation, sampling and testing program may fail to detect all or certain archaeological resources. The sampling strategies incorporated in this study comply with those identified in the Ministry of Tourism and Culture's *Standards and Guidelines for Consultants Archaeologists* (Government of Ontario 2011).

11.0 CLOSURE

We trust that this report meets your current needs. If you have any questions, or if we may be of further assistance, please contact the undersigned.

APPENDIX B

Pre-contact Aboriginal Glossary of Terms/Definitions

Chipped lithic tools and debitage were found at the site (or sites) described in this report. Some of the more common chert types found on pre-contact Aboriginal sites in southern Ontario are described below.

Kettle Point chert: a relatively high quality raw material found within the Upper Devonian age Kettle Point Formation that outcrops between Kettle Point and Ipperwash, on Lake Huron. Currently, Kettle Point occurs as submerged outcrops extending for approximately 1,350 metres into Lake Huron. Secondary deposits of Kettle Point chert have been reported in Essex County and in the Ausable River watershed (Eley and von Bitter 1989; Fox 2009:362).

Onondaga chert: a high quality raw material found within the Onondaga Formation that outcrops along the north shore of Lake Erie west of the mouth of the Grand River as far west as Nanticoke, east of the mouth of the Grand River as far east as Fort Erie, and along the Onondaga Escarpment between Cayuga and Hagersville (Telford and Tarrant 1975). This material can also be recovered from secondary, glacial deposits across much of southwestern Ontario, east of Chatham (Eley and von Bitter 1989; Fox 2009:361-362).

Selkirk chert: a moderate to relatively high quality raw material that occurs within the Dundee Formation; it outcrops along Sandusk Creek and its tributaries just west of the village of Selkirk (Telford and Tarrant 1975). The chert ranges in colour from mottled or banded grey to a predominantly brown colour, the latter of which being of relatively more vitreous fabric than the former. Its distribution as a secondary source material is similar to Onondaga chert and it is frequently encountered as far west as the Chatham area (Eley and von Bitter 1989; Fox 2009:362).

Non-chert: some materials other than chert were occasionally used for the manufacture of chipped tools, and consequently some pieces of non-chert debitage may occur on some sites. Materials in the non-chert category may include quartzite, quartz-like materials, schist and slate or shale.

All chert types discussed herein were identified visually by comparison to reference materials located in Golder's London offices. The flake assemblage was subject to morphological analysis following the classification scheme described by Lennox et al. (1986) and expanded upon by Fisher (1997), with the exception that no attempt was made to distinguish "primary" from "primary bipolar" flakes.

With reference to the analysis of lithic debitage, the following overview provides descriptions of the various types of cores and debitage commonly found on pre-contact Aboriginal sites.

Cores: Pieces of stone (usually chert) from which flakes or blades have been removed. A core may be uni-facetted (flake removed from one surface or edge only) or multi-facetted (flakes removed from two or more surfaces or edges. A core may retain a segment of its exterior, weathered surface.

Primary Reduction Flakes: are by-products of the initial stages of the reduction of lithic material, they are derived from cores and are generally attributed to direct hard hammer percussion. Primary flakes may exhibit a large cortical striking platform. This platform may appear on an otherwise unmodified flake scar or a crushed flake margin. Where measureable the striking platform – ventral surface angle is approximately 90 degrees, usually unfacetted and large. Ventral surface attributes are usually well pronounced while the dorsal surface consists of 50-100% cortex, implying little or no modification of the core prior to the removal of the primary flake.

Primary Thinning Flake: a large, thick flake with an unprepared striking platform and few to no flake scars on its dorsal (exterior) surface. These flakes are typically thinner than Primary Reduction Flakes. Their platform is

usually large, flat or minimally facetted, and close to 90 degrees. A Large bulb of percussion is common on the ventral side. Primary Thinning Flakes are typically associated with the hard hammer percussion method from the initial stage of chipped stone tool production.

Biface Thinning Flake: a moderately thick to thin flake with a small platform that can be ground and/or faceted to some degree. The platform angle is usually acute or less than 90 degree. The dorsal side of the flake often has seveal shallow intersecting scars with no cortex material remaining. Biface Thinning Flakes are associated with the medial stage of biface reduction where a stone tool is thinned through the removal of flakes from opposing surfaces.

Retouch Flakes: small, thin flakes removed from the edge of a stone tool or larger flake through pressure flaking. These flakes tend to have a small, lipped platform that may exhibit crushing or part of a dulled bifacial edge. The dorsal surface typically displays flake scars from previous removals and lacks cortex material. They are associated with the final stage of chipped stone tool production when edges are sharpened and notches for hafting are created. They are also associated with maintenance activities where tools are re-sharpened and broken edges rejuvenated.

Shatter: usually consists of thick, blocky pieces of chert which lack striking platforms and ventral flake surface attributes. This category of debitage is thought to be a by-product of the initial stages of reduction through the uncontrolled breakage of the raw material along structural faults or irregularities. They commonly result from the use of horizontally and vertically flawed material, these flaws apparently a result of stresses occurring to the material while still within its primary deposit. A relatively high incidence of shatter is usually associated with the bipolar reduction strategy.

Flake Fragments: are broken flakes with no platform or proximal end. They cannot be convincingly linked to any particular lithic activity. As such, they have very little analytical value.

Micro flake: Very small broken flakes are classed as micro flakes, less than 3mm in size. These flakes are small and generally only recovered from floatation samples.

The following glossary defines some of the terms for some of the formal and informal chipped lithic tools from the sites discussed in this report. All of the definitions are derived from a reputable online sources such as www.archaeologywordsmith.com . and www.wvculture.org/shpo/glossary.html.

Artifact: “any object made, modified or used by people”.

Biface: “a stone tool which has been flaked on both surfaces or sides”; frequently made as roughed-out blanks or preforms intended for further reduction into finished tools such as projectile points or knives.

Burin: “from the French word *burin*, meaning cold chisel. A specialized engraving tool … that is cut or ground [or flaked] diagonally downward to form a diamond-shaped point at the tip… In its most characteristic form, the working tip is a narrow transverse edge formed by the intersection of two flake scars produced by striking at an angle to the main axis of the blade… Burins were used to carve or engrave softer organic materials such as antler, bone… or wood”.

Debitage: “the by-products or waste materials left over from the manufacture of stone tools”.

Diagnostic artifact: “an item that is indicative of a particular time period or cultural group”.

Drill: “a tool used to drill holes through or into wood, stone or bone”.

Ecofact: “nonartifactual evidence that has not been technologically altered but that has cultural relevance.”

Graver: “a stone tool manufactured from a flake by chipping (pressure-flaking) it on two edges at one end so as to leave a sharp point. Gravers were used to cut or score organic materials such as bone, shell, wood and antler; perhaps for punching leather, and other purposes”.

Lithic: “stone, or made of stone”.

Knife: a purposefully formed cutting tool.

Perforator: “a flint [chert] tool for piercing holes”, or, “a small chipped stone implement with a rather long and slender point and usually a broad base, supposed to have been used for drilling or boring holes”. Perforators are sometimes referred to as borers.

Projectile point: “a general term for points [usually stone] that were hafted to darts, spears or arrows”; commonly referred to as either spearhead or arrowhead.

Retouched flake: “a flake that has had small flakes removed to blunt, sharpen, refine the outline or prepare the edge of the tool”.

Scraper: a stone tool formed by chipping [flaking] the end or side of a flake which can then be used to scrape animal hides or wood.

Spokeshave: “a stone tool with a semi-circular concavity on the edge, used for smoothing spear or arrow shafts; a drawknife or small transverse plane for planning convex surfaces”.

Utilized flake: “a piece of stone debitage that is used for cutting or slicing. The edge may be damaged from use, but not deliberately”.

Wedge: “an object used to split, force open or keep open another object; a tool used to split wood”.

Stages of Reduction for Chert Bifaces (based on Fisher 1997:25-29)

There have been several different approaches to the definition of the stages of biface reduction, in both Eurasia (Andrefsky 2005:32) and North America (i.e. Callahan 1979: 30-31). Many Ontario-based researchers have adopted the classification scheme used by Fisher (1997: 25-29), which was based largely on Callahan (1979: 30-31). Fisher's definitions of Stage 1 (initial) through Stage 4 (final) bifaces take into consideration characteristics such as number and size of flakes removed, length and depth of flake scars, cross-section, length-width ratio, and edge configuration.

Stage 1: During this initial stage of biface reduction specimens are only roughly shaped. The biface cross-section is hexagonal, irregular to thick lenticular, and is not plano-convex at all (Callahan 1979:36). Biface thinning flake scars are deep, large and generally do not cross half of the biface width, leaving remnants of the original material surface. From a lateral view, the edge of the biface is jagged and highly irregular.

Stage 2: At this stage the biface is still relatively thick compared to its width, with more lateral flake removals crossing over half the biface width, leaving less of the original surface present. As well, thinning flakes are more numerous and smaller. The edge of the biface is still irregular, but less jagged.

Stage 3: This stage of reduction produces a biface with a lenticular cross-section, thinning flakes are shallow and are consistently greater than half the biface width. Also, there is a greater regularity to the edge, and bases may be formed, if only incipiently, on some specimens.

Stage 4: Stage 4 is represented by an almost finished projectile point with a relatively high width to thickness ratio, a relatively regular or even edge, some retouch, and a shaped base. Some items classed as Stage 4 specimens may have been finished projectile points. However, they are not as finely crafted as the definitive finished projectile points, perhaps due to material or knapping flaws, or skills of knappers.

APPENDIX C

Historic Euro-Canadian Glossary of Terms/Definitions

Applied and Hand-Tooled Finishes: Between circa 1830 and 1885 the most common way of creating the opening, or finish, of a bottle was to apply a variably thick string of glass at or immediately below the blowpipe removal point, which was then manipulated with a finishing tool to form a wide variety of finishes (Lindsey 2015).

Applied Colour Labels: a method of labelling, lettering, or decorating a glass container by applying enamel through a metal screen and then baking the enamel in a furnace to form a more or less permanent label (Lindsey 2015). First invented in the 1920s, applied colour labels gained wide-spread acceptance by circa 1935.

Ball Clay: A fine dark kaolinic clay that turns white or nearly white when fired, used in the manufacture of a wide variety of ceramic wares in combination with other clays for its exceptional bonding properties and plasticity.

Coarse Red, Yellow, and Buff Earthenwares (CRE, CYE, CBE): manufactured throughout the late 18th and 19th centuries. They were the most common utilitarian wares during the first half of the 19th century and continue to be produced today (Adams et al. 1994). Both ware types are generally somewhat porous and hard, with the red variety having an orange to red colour and the yellow variety having a buff to yellow colour. As these wares are quite porous, glaze is needed in order for the vessel to hold liquid contents.

Cup-bottom mould: the separate base part of a bottle mould. The resulting base resembles a shallow depression or cup that attaches onto the body of the bottle. As such, the base seam forms a horizontal line around the heel of the bottle. Generally this type of mould is found on two-piece vertical moulds and machine made bottles, dating ca. 1850 to the present (Jones and Sullivan 1985:45). Cup-bottom moulds became the dominant mould type used for mouth-blown bottles from the late 1880s to the late 1910s when automatic bottle machines began to dominate the industry (Lindsey 2015).

Cut Nails: were machine cut from flat sheets of iron creating a nail that is of even thickness when viewed from the side, not tapered on all sides like hand-made nails, with a square and flat head. Invented about 1790, cut nails were in common use from the 1830s until the 1890s (Adams et al. 1994: 94).

Edged Wares: Tablewares were often decorated with moulded rim motifs that were usually painted under the glaze in blue or green, and occasionally red (Miller 1991). This method of decoration, simply referred to as ‘edged’ by 19th century potters, was first introduced in the 1770s. By the 1840s, green edged wares became rare, while blue edged wares remained popular into the 1860s and continued to be available for purchase well into the 1890s and possibly later (Miller 1991). The moulded motifs present on edged wares changed through time with scalloped or undulating rims occurring prior to 1840 and unscalloped rims occurring after 1840. Unscalloped edged wares remained popular until the 1870s (Adams et al 1994:102; Miller 1987).

Flow Transfer Printed Wares: Created by placing volatizing chemicals, such as lime or ammonium chloride, in the kiln during the glaze firing process, flow wares are characterized by the appearance of painted and printed colours flowing beyond the borders of the original pattern, producing a halo-like effect. Although first introduced by Staffordshire potteries in the 1820s, flow wares did not appear in North American until 1844 (Collard 1967:118, Miller 1991:9). Flow wares were commonly produced between the 1840s and 1870s; however, some potters continued to produce this ware type as late as the early 20th century (Collard 1967:118). The most common colour used in the flow process was blue, though vessels were also decorated in purple, brown, black and green palettes (Collard 1967:118). Stylistic motifs commonly found on flow wares included Chinoiserie, floral, and romantic designs.

Glass Containers: occur in a wide variety of shapes, sizes and colours. In archaeological assemblages (particularly those recovered from agricultural fields), glass containers are usually highly fragmented, thus making identification difficult. Frequently, container glass sherds can only be classified according to colour. Occasionally archaeological assemblages will also produce either relatively complete glass containers or glass container fragments that exhibit temporally diagnostic manufacturing and/or decorative characteristics. These characteristics are often found on the finish/neck, body, and base/heel of glass containers (Adams et al. 1994).

Hand-Tooled Finish: A method of creating the opening, or finish, of a bottle whereby the glass of the finish-to-be is typically blown with the rest of bottle, not added in a separate hand application as with the applied and hand tooled finishing method. Once the blowpipe was severed from the bottle neck, the finish was shaped by reheating the glass and forming the shape with a finishing tool. This method of finishing a bottle was first introduced in the 1870s, but was particularly common after 1885. The method largely disappeared between 1910 and the early 1920s when semi-automatic and later fully automatic bottle making machines began to dominate the market place (Lindsey 2015).

Lithograph/Decal Wares: The lithographic decorative process for ceramics entails applying a design in the form of a paper-backed sheet to the surface of a vessel that has first been covered in a layer of tacky varnish. The backing paper is then sponged off. There were endless assortments of lithographic patterns, which were generally many different colours and often included much shading. This type of decoration became popular during the late 19th century (1890s) and early 20th century and is in common use still today (Savage and Newman 1974). Decals remained the most common technique for decorating ceramics well into the 1950s.

Machine Made Glass Containers: Machine made glass containers will often exhibit several diagnostic characteristics that assist in their identification (Lindsey 2015), including: vertical side mould seams that extend to the highest point of the finish and often onto the extreme top finish surface; side mould seams that appear sharper and finer; mould seams around the top and bottom of the finish; “ghost” seams which may be present along the neck, should, and/or body of containers manufactured in a blow-and-blow machine; suction scars present on the base of containers produced by the Owen’s Automatic Bottle Machine; valve marks on the bases of containers manufactured by the press-and-blow machine; and, very few bubbles present in the glass.

Manganese Tinted Glass: Although typically the colour of container glass alone is very limited in its ability to provide a manufacturing date for a container (Lindsey 2015; Jones and Sullivan 1989:12-14), studies have suggested that most manganese tinted, or purple coloured, glass typically dates between 1880 and 1920 (Miller 2000:8; Lockhart 2006). During this time, manganese was often added during the manufacturing process to produce colourless glass. However, due to the presence of the manganese, the glass would turn light purple in colour over time when exposed to sunlight.

Moulded Vitrified White Earthenware: Vitrified white earthenware is often decorated with raised moulded designs. The most popular and enduring of these was the “wheat” or Ceres, pattern, which in addition to other harvest or grain motifs, was popular from the 1860s to the turn of the 20th century (Sussman 1985). Other common moulded motifs include foliage, geometric, paneled/scalloped, classical, and ribbed. Broadly speaking, up until the 1870s, potters produced wares with detailed molding or sharp angles. After this period, the use of moulded motifs decreased or disappeared and vessel lines became simpler (Wetherbee 1996:10).

Owen’s Machine: The Owen’s machine was the first fully automatic glass bottle-making machine where molten glass is sucked into a mould via a vacuum to form a bottle, dated to 1904-1950. The process leaves a distinctive

'feathery-edge' scar on the base of the bottle, known as an Ownen's suction scar. (Jones & Sullivan 1989:38-39).

Owen's Suction Scars: are a distinctive basal feature on a glass bottle made with an Owen's machine. The scar is circular to ovoid and is "feathered", i.e., small striations radiating away from the circular mark. Bottles with Owen's suction scars date no earlier than 1904 and typically date after about 1910 when the Owen's machine began its climb towards the dominance of the bottle market (Jones and Sullivan 1989:38-39; Lindsey 2015).

Painted Wares: White-bodied earthenwares decorated with underglaze painted motifs first became common in the late 18th century (Miller 1991). Painted wares made before about 1830 typically feature designs that were either painted in all blue or in a polychrome palette featuring blue, brown, yellow, and green; these colours are referred to as "early palette" colours. By the 1830s, chrome based pigments, also referred to as "new or late palette" colours, became popular, expanding the variety of colours appearing on painted wares to include black, bright green, and red. Painted wares remained popular until the 1870s (Adams et al. 1994; Hughes 1961).

Parison Mould Seams: Off-centre, usually incised circles that appear on the bases of bottles are characteristic of 20th century machine-made bottles. These marks are introduced by the parison/blank mould portion of various semi-automatic and fully automatic machines (Lindsey 2015).

Porcelain: is a type of earthenware fired at such a high temperature that the clay has begun to vitrify; consequently the ceramic is translucent when held up to a light (Kenyon 1980). Because of its high cost, porcelain is extremely rare on 19th century sites in Ontario. However, by the turn of the century it becomes relatively common as production techniques were developed in Europe which greatly reduced costs.

Post-bottom Mould: the separate base part of a bottle mould that results in a well-formed, centred concavity in the bottom of the bottle. As such, the two vertical side seams attach to a circular seam centered on the bottle base. This type of mould is found on containers formed in a mould of any number of (Jones and Sullivan 1985:45). Post-bottom moulded bottles were used in the U.S. at least as early as the 1840s and as late as the early 1900s for mouth-blown bottles. It was the dominant bottle mould type during the last third of the 19th century (Lindsey 2015).

Progressive Box System: The progressive box dating system involves moulding various combinations of lines on the bases of bottles before the trademark. These line combinations were used to indicate a specific two-month period of manufacture. The progressive box dating system replaced the letter/number dating system in 1953 (Miller and Jorgensen 1986).

Prosser Buttons: are small glass-like ceramic buttons manufactured by the Prosser process. The Prosser process involves pressing powder into moulds and then firing it at high temperatures to produce a hard button. They are characterized by a smooth top side, a stippled or "orange peel" textured bottom and a noticeable seam around the edge. Prosser buttons post-date 1840 (Sprague 2002: 111).

Refined White Earthenware: is slightly porous, white-pasted earthenware with a near colourless glaze that replaced earlier near white ceramics, such as pearlware and creamware, by the early 1830s. The use of refined white earthenware continued throughout the 19th century, and is still used today, but its popularity began to decline by the 1840s with the introduction of ironstone and vitrified white earthenware (Adams et al 1994; Miller 2000:10, 13).

Rockingham Ware: is a light to yellow coloured earthenware or stoneware splattered with a brown manganese glaze applied to a piece already covered with a clear glaze (Claney 2004:32; Stradling 2005:11). This ware type, which was commonly used from the mid-19th to early 20th centuries, was an inexpensive, mass produced ware manufactured in both England and North America (Claney 2004:xiii).

Side Mould Seams: Glass containers with side-mould seams that extend over the lip are characteristic of 20th century machine-made containers (Jones and Sullivan 1989:38). Conversely, the tops of bottles manufactured in the 19th century were typically finished by hand so that the seam did not extend to the lip.

Slipped/Dipped/Banded Wares: Slipped wares are defined by their brightly colored and often exuberant surface decoration. These surface decorations were created using clays that had different colors when fired or that were dyed by the addition of mineral oxides suspended in a liquid solution known as slip. Slip could be used as a dip for the entire surface of the vessel or as a substance with which to pour, band, drip or trail designs. Other designs were created by removing slip in a variety of cut designs with an engine turned lathe to expose the ceramic body underneath. Slipped wares were the cheapest hollowware with color decoration available to consumers from the 1780s through the 19th century. With the exception of engine turned dipped wares and simple banded decorations that were produced throughout the 19th century, slipped wares are not common after the 1840s (Miller 1991).

Smoking Pipes: White clay pipes were very popular throughout the 19th century, with a decline in use by 1880 when they were replaced by briar pipes and cigarettes. Most white clay pipes found in Upper Canada were manufactured in either Quebec or Scotland, while examples from English, Dutch, French and American makers are also occasionally found. Sometimes the maker's name and or city of manufacture were impressed on one side of the pipe stem, a practice which did not become popular until the 1840s (Adams et al. 1994).

Sponged Wares: were a form of inexpensive tableware in which a sponge was used to apply an underglaze pigment. All-over sponging became popular by the 1840s and remained common until the 1870s (Adams et al. 1994:102).

Stamped Wares: A variety of the sponged method, stamping involves cutting a sponge into simple designs (e.g., geometric, leaves, flowers). These stamps were then loaded with pigment and repeatedly dabbed around the ceramic to form a coarse but often pleasing design. This technique was used from 1845 to 1930 (Miller 2000:13).

Stippling: is a mould induced feature commonly found on the bases of glass containers. Applied to bottles for both aesthetic and practical reasons, stippling became a common feature on the bases of glass bottles and jars in the mid-20th century (Lindsey 2015).

Stoneware: is a hard, heavy, grey to light brown ceramic that was commonly used for utilitarian purposes (i.e., crocks and jugs). It is fired at a higher temperature than earthenware and has a less porous body. The exterior of stoneware vessels often has a salt-glaze which gives it a dimpled or "orange-peel" effect. If the crock was intended to hold liquid, the interior may have a thick dark brown coating, known as an Albany slip, which was used on stoneware vessels from about 1805 to 1920 (Miller 2000:10). By the late 19th century, some stoneware items were coated on the exterior with a thick white or brown "Bristol" glaze. Stoneware was not made in Ontario until 1849 (Adams et al. 1994).

Straw Tinted Glass: is another bottle glass colour which can assist in dating an artifact assemblage. Although occasionally found on bottles manufactured in the late 19th century, straw tinted glass bottles are mostly diagnostic of machine-made bottles manufactured as early as 1912 and no later than the 1950's (Lindsey 2015). The straw coloured tint observed in the glass is indicative of the presence of selenium or arsenic, which were both used as de-colourizing agents during the manufacturing process.

Transfer Printed Wares: First introduced in 1756, the technique of transfer printing designs to the underglaze surface of clay ceramics revolutionized the British ceramic industry (Birks 2005). This process, which involved transferring a design from an engraved and inked copper (or other metal) plate to a ceramic vessel with a piece of special tissue, allowed potters to apply intricate patterns quickly and rather inexpensively, allowing for more uniformity between vessels (Samford 1997). Transfer printed wares remained popular until the mid-19th century when minimally decorated wares, such as ironstone, became popular. Transfer printed wares enjoyed a brief revival beginning in the 1870s, which lasted until lithographs, or decals, became popular in the early 1900s. In terms of colour, earlier transfer printed wares were mostly blue, and less densely decorated with more of the white background showing through the designs. After 1830, colours such as light blue, brown, black, sepia, green, red and mulberry became more common (Collard 1967; Coysh and Henrywood 1982:10). From about 1850 to 1890 only the colours blue, black, and brown were common, while in the 1890s and later a wide variety of colours were in use (Adams et al. 1994:101). Brown transfers are considered very common and were the least expensive of all the colours (Birks 2005).

Valve Marks: are circular impressions that appear on the bases of bottles manufactured by press-and-blow machines. These marks were formed by machines that used a push-rod valve to eject the partially expanded parison out of the blank mould to be transferred to the second blow mould. These marks typically appear on wide-mouthed bottles dating from circa 1894 to the 1940s (Lindsey 2015).

Vitrified White Earthenware: also known as white granite, graniteware, white stone ironstone, semi-porcelain, or simply ironstone, is a variety of white bodied earthenware with a white to greyish-white fabric that is usually thick and heavy beneath a thick, hard clear glaze with a white, greyish or bluish tint. Vitrified white earthenware was first developed in the 1840s, but did not become popular until the second half of the 19th century. Its popularity continued into the 20th century and it is still in use to some extent today.

White Glass: was most commonly used for cosmetic containers, toiletry bottles or cream jars. The opaque white glass was very commonly used for such products dating from about 1870 through to the 20th century (Lindsey 2015).

Willow Pattern: First developed in 1792, the "willow" pattern includes a bridge, a cottage or pagoda, three figures, a boat and two birds, which combined together, tell a story. A geometric border is also usually included with the willow pattern. This pattern was common in the first half of the 19th century, but still remains popular today (Noel Hume 1976:130-131, 260-261).

Window Glass: During the 19th century, window glass was produced by the cylinder glass technique. A molten ball of glass was blown into a sphere, and then swung into a cylinder shape. While the glass was still workable, the cylinder's ends were cut off, and the cylinder was cut along its length forming two curved panes, which were then flattened, cooled and cut into smaller panes (Weiland 2009:29). Over the course of the 19th century, the demand for larger windows increased resulting in thicker windows. The chronological variability in the thickness of window glass has been applied as a dating method for archaeological sites; however, it has been determined

that the accuracy of this dating method is largely dependent upon the presence of relatively large sample sizes and the availability of regionally developed chronological models (Jones and Sullivan 1989:172).

Wrought Nails: are hand made with hammered heads and their sides taper to a point. Wrought nails were the most common nail type before 1830 (Adams et al. 1994:94).

Wire Drawn Nails: are identical to the type of nails in current use today, with a flat, round head and a wire shaft. Wire drawn nails were developed in the 1850s but did not become popular until the 1890s (Adams et al. 1994).

Yelloware: is earthenware made from naturally coloured buff/yellow clay, covered with a clear glaze. Glazed wares vary from brownish mustard to light yellow (Sussman 1997:77). This ware type was primarily used for food preparation and storage, and dates from 1830 to 1940 (Miller 2000:12), with its peak popularity after 1850 (Burke 1991:35).
